

Understanding the Diagnosis of Atrial Fibrillation and How to Prevent Stroke

UpBeat
By Heart Rhythm Society

You or your loved one may have been diagnosed with Atrial Fibrillation. **You should know that you are not alone.** There are many people around the world with this condition. It is the most common heart rhythm condition.

This diagnosis comes with many questions and terms that may be hard to understand.

After reading the information below, we hope that you will feel more comfortable:

- Taking an active role in your treatment decisions
- Having open and honest conversations with your doctor about your concerns

The Basics of Atrial Fibrillation

WHAT IS ATRIAL FIBRILLATION?

Atrial Fibrillation, AFib for short, is a problem with how your heart beats. With AFib, your heart may beat too fast, switch back and forth from fast to slow, or skip beats. We call this type of heartbeat “irregular.” AFib may start suddenly and then stop on its own, or it may become a long-lasting problem.

With AFib, your heart can't pump blood out to your body in a normal way. AFib is an illness that can become worse if it's not treated.

This type of irregular heartbeat gives you a higher risk of stroke and other heart problems.

“In 2017, at least **37.5 million** people were living with AFib around the world.

HOW AND WHY DO PEOPLE GET AFIB?

Sometimes the reason people get AFib is unknown. Other times, the system that signals the heart to beat is damaged. Different problems may cause this damage, with the most common being:

Heart-related problems such as

- High blood pressure
- Coronary artery disease
- Heart failure
- Heart valve disease
- Heart surgery (AFib is the most common complication after heart surgery)

Other problems such as

- Sleep apnea
- Thyroid disease
- Lung disease or lung cancer
- Drinking too much alcohol
- Being seriously ill or having an infection

Some people are more likely to get AFib than others. You have a higher chance of getting AFib if:

- You are older than 60
- You smoke
- You have diabetes
- You are overweight
- You have a family history of AFib
- You exercise often and hard

Even people with healthy lifestyles who have no other medical problems can get AFib.

WHAT ARE THE SIGNS AND SYMPTOMS OF AFIB?

The signs and symptoms of AFib are different from person to person. Some people with AFib feel no symptoms at all. They might not even know they have AFib or that there is a problem. Others can tell as soon as it happens. AFib symptoms can be bothersome and frightening.

Signs and symptoms include:

- Feeling overtired or having little to no energy
- Having a faster-than-normal heartbeat or a heartbeat that switches between fast and slow (irregular)
- Having shortness of breath
- Feeling like your heart is racing or pounding
- Finding everyday exercises or activities harder than usual
- Having chest pain, pressure, tightness, or discomfort
- Feeling dizzy or lightheaded, or fainting

It's important to see a doctor early if you have symptoms of AFib. Make an appointment if you notice something different or bothersome with your heartbeat.

HOW IS AFIB DIAGNOSED?

If your doctor thinks you may have AFib, the first thing they'll do is ask you questions about your symptoms and listen for an irregular heartbeat through a stethoscope. **They may also do tests to be sure of the diagnosis. The tests will help them figure out the reason for your irregular heartbeat and the best way to treat it.**

A few tests can be done to check for an irregular heartbeat. **An ECG or EKG for short, is a simple, painless test that is the most helpful in diagnosing AFib.**

It can measure how fast your heart beats and the type of heartbeat you have. It can also measure the timing of the signals passing through your heart.

An ECG can be done in a doctor's office. During this test, special stickers, called electrodes, are temporarily attached to your chest, arms, and legs. The electrodes pick up signals from your heart. **The ECG test gives your doctor a picture of your heart's activity.**

Sometimes, the ECG done in the doctor's office does not catch your AFib, and a test that lasts longer is needed. In this case, your doctor will ask you to wear a special monitor or a mobile device to keep track of your heart over a longer period of time.

WHAT IS THE TREATMENT FOR AFIB?

Once you are diagnosed with AFib, you and your doctor will make a treatment plan that is right for you. Your treatment plan may include being referred to a heart specialist, which might be a general cardiologist or a cardiologist that treats heart rhythm problems (electrophysiologist).

AFib can be treated in different ways. Treatments such as medications, non-surgical procedures, and surgery can slow down your heartbeat and bring it back to normal. Since AFib can cause blood clots to form in the heart, and the clots could then cause a stroke, patients are also often prescribed blood thinners to prevent blood clots from forming.
